

Calibration of High Temperature Thermal Conductivity System

New Algorithm to Measure Heat Capacity using Flash Thermal Diffusivity in Thermoelectric Materials

**Rahul Deb – Caltech SURF Fellow
Mentor: Dr. Jeffrey Snyder
Jet Propulsion Laboratory**

Presentation Map

- **Introduction**

- Thermoelectric Materials Background
 - Research Goal & Heat Capacity Measurements

- **Process**

- Flash Thermal Diffusivity

- **Experiments**

- Stainless Steel Comparison
 - Pulse Max Integral Fit
 - Graphite Comparison Algorithm

- **Conclusion**

What are Thermoelectrics?

- Materials that are power generators or coolers depending on their use
- Case 1:
Heat gradient  electron flow = current
- Case 2:
Current flows  reverse heat gradient = refrigerator

Thermoelectric Applications

RTGs in Space Missions

Peltier Coolers

Waste Heat Automobiles

Direct Power Source

Improving Thermoelectrics

- Limiting use factor: only 4-6% efficiency
- 2 ways to improve thermoelectrics:
 - Develop more efficient materials
 - Improve Measurement Systems

Research Goal

- Improve the figure of merit calculation for thermoelectrics by improving the accuracy of heat capacity measurements

- $$z T = \frac{\alpha^2}{\rho \alpha' C_p d}$$

C_p - heat capacity α - Seebeck coefficient

ρ - electrical resistivity α' - thermal diffusivity d - density

- **Improved heat capacity, C_p , measurements will directly improve the thermoelectric figure of merit**

Flash Thermal Diffusivity

$$C_p = Q / (m * \Delta T)$$

Background Effects

**3 Sources Found to Affect
Detector Readings**

Addition of LN_2

Lab Temperature

Cooling Water Temperature

**Shield used to minimize some background, but
effects not sufficiently removed**

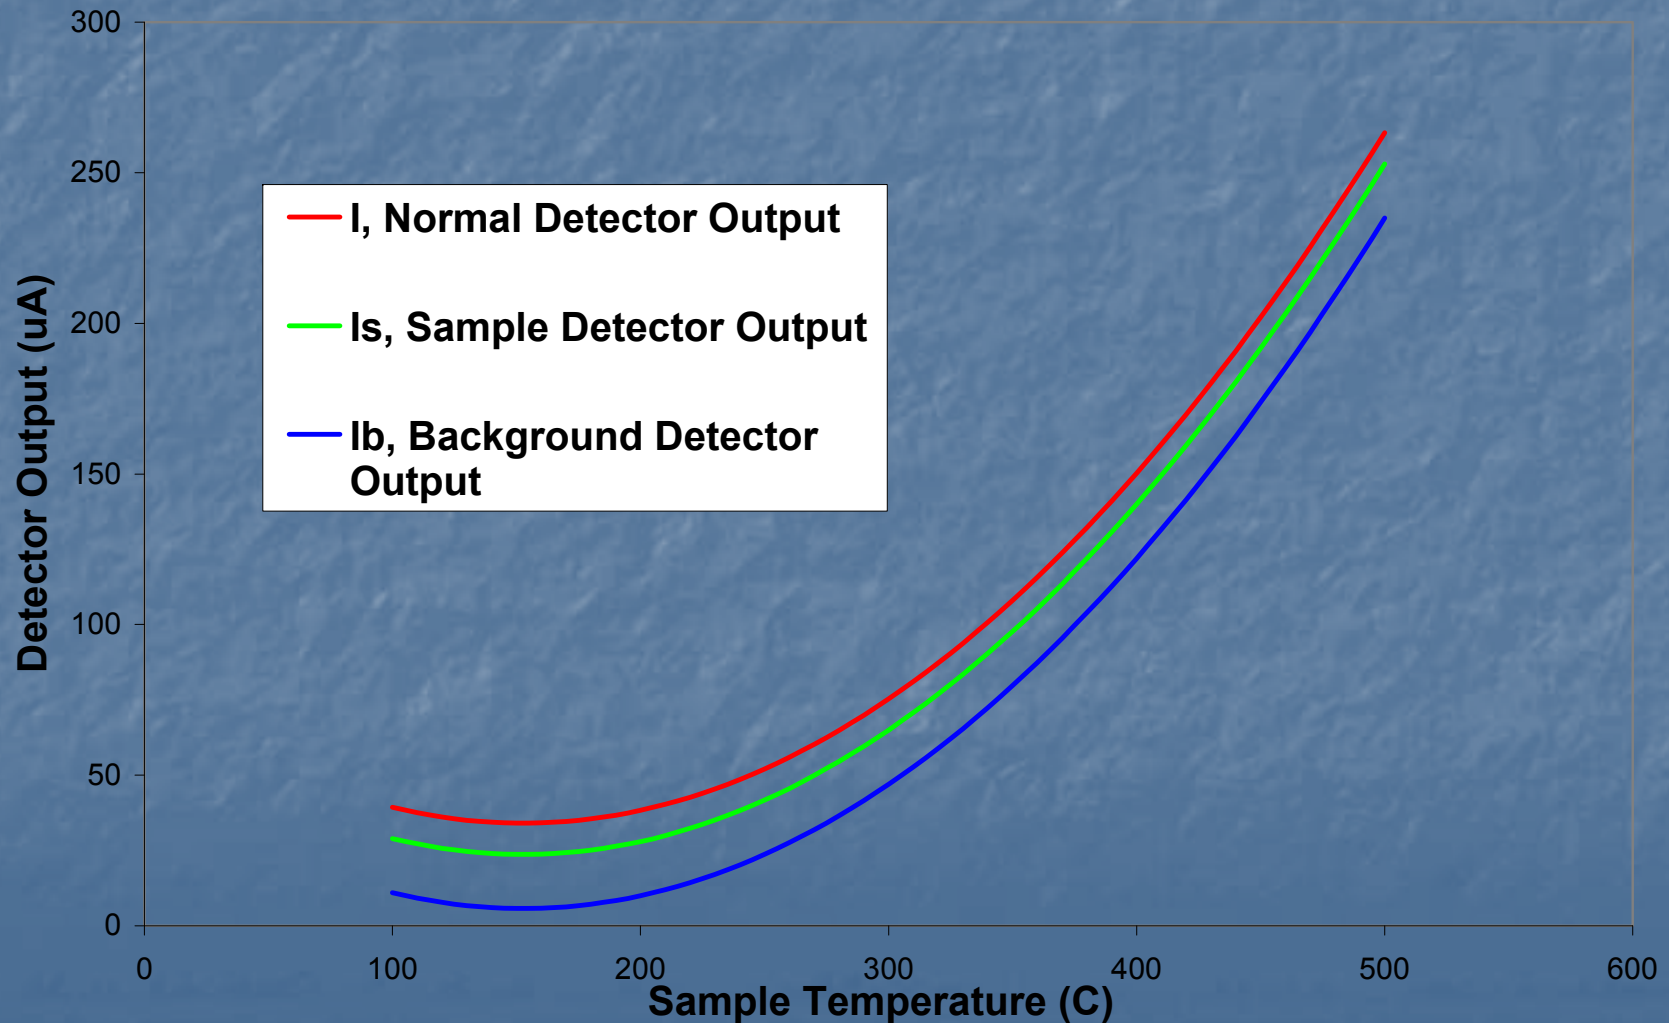

Stainless Steel Comparison

Experiment 1

- Measurement: I_D - Detector Output
- Hypothesis: $I_D = I_B + I_S$
- If I_B removed, just have sample temperature → eliminates background effects seen earlier

Stainless Steel Comparison

Theoretical Detector Outputs vs. Sample Temperature

Stainless Steel Comparison

Sample 1

Sample 1 fully coated in graphite, emissivity is 1, Detector should pick up normal output, I_D

Input signal from xenon flash

Sample 2

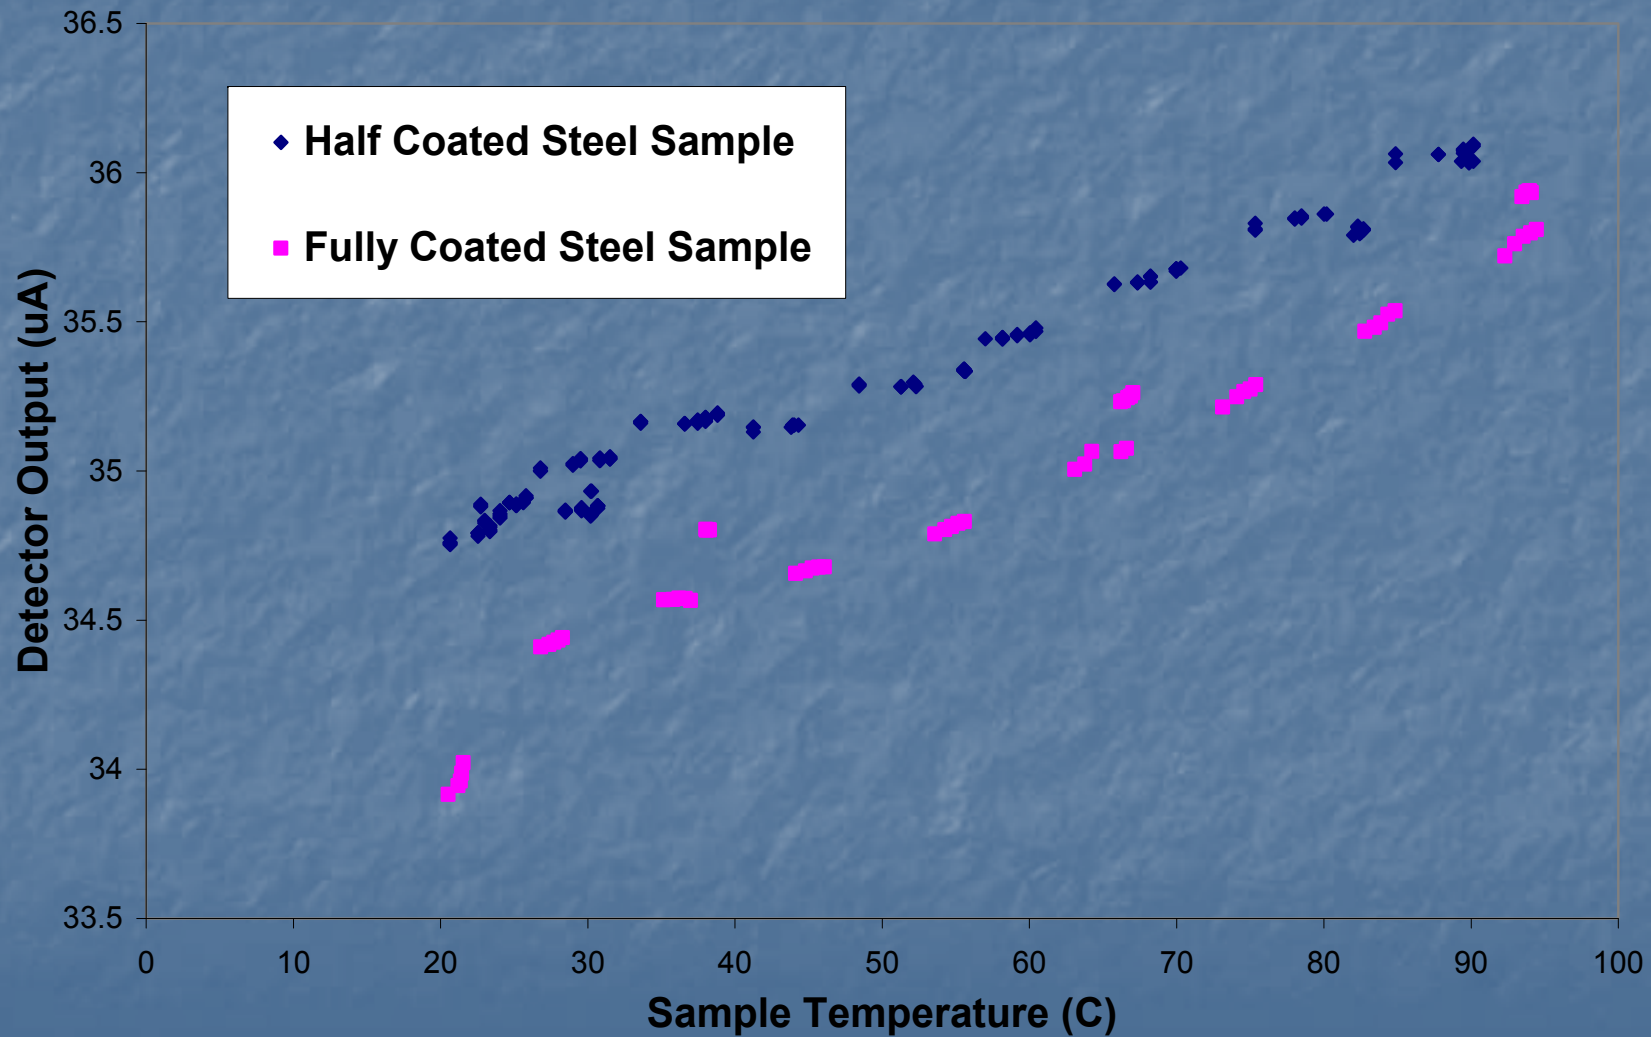

12 mm

1 mm

Sample 2 was left uncoated on one half, the emissivity is 0, so no output signal. Any signal detector picks up should be background, I_B

Stainless Steel Comparison

Detector Output vs. Sample Temperature

Results of this experiment did not match hypothesis

Pulse Max Integral

Experiment 2

- Measurement: P – Pulse Max

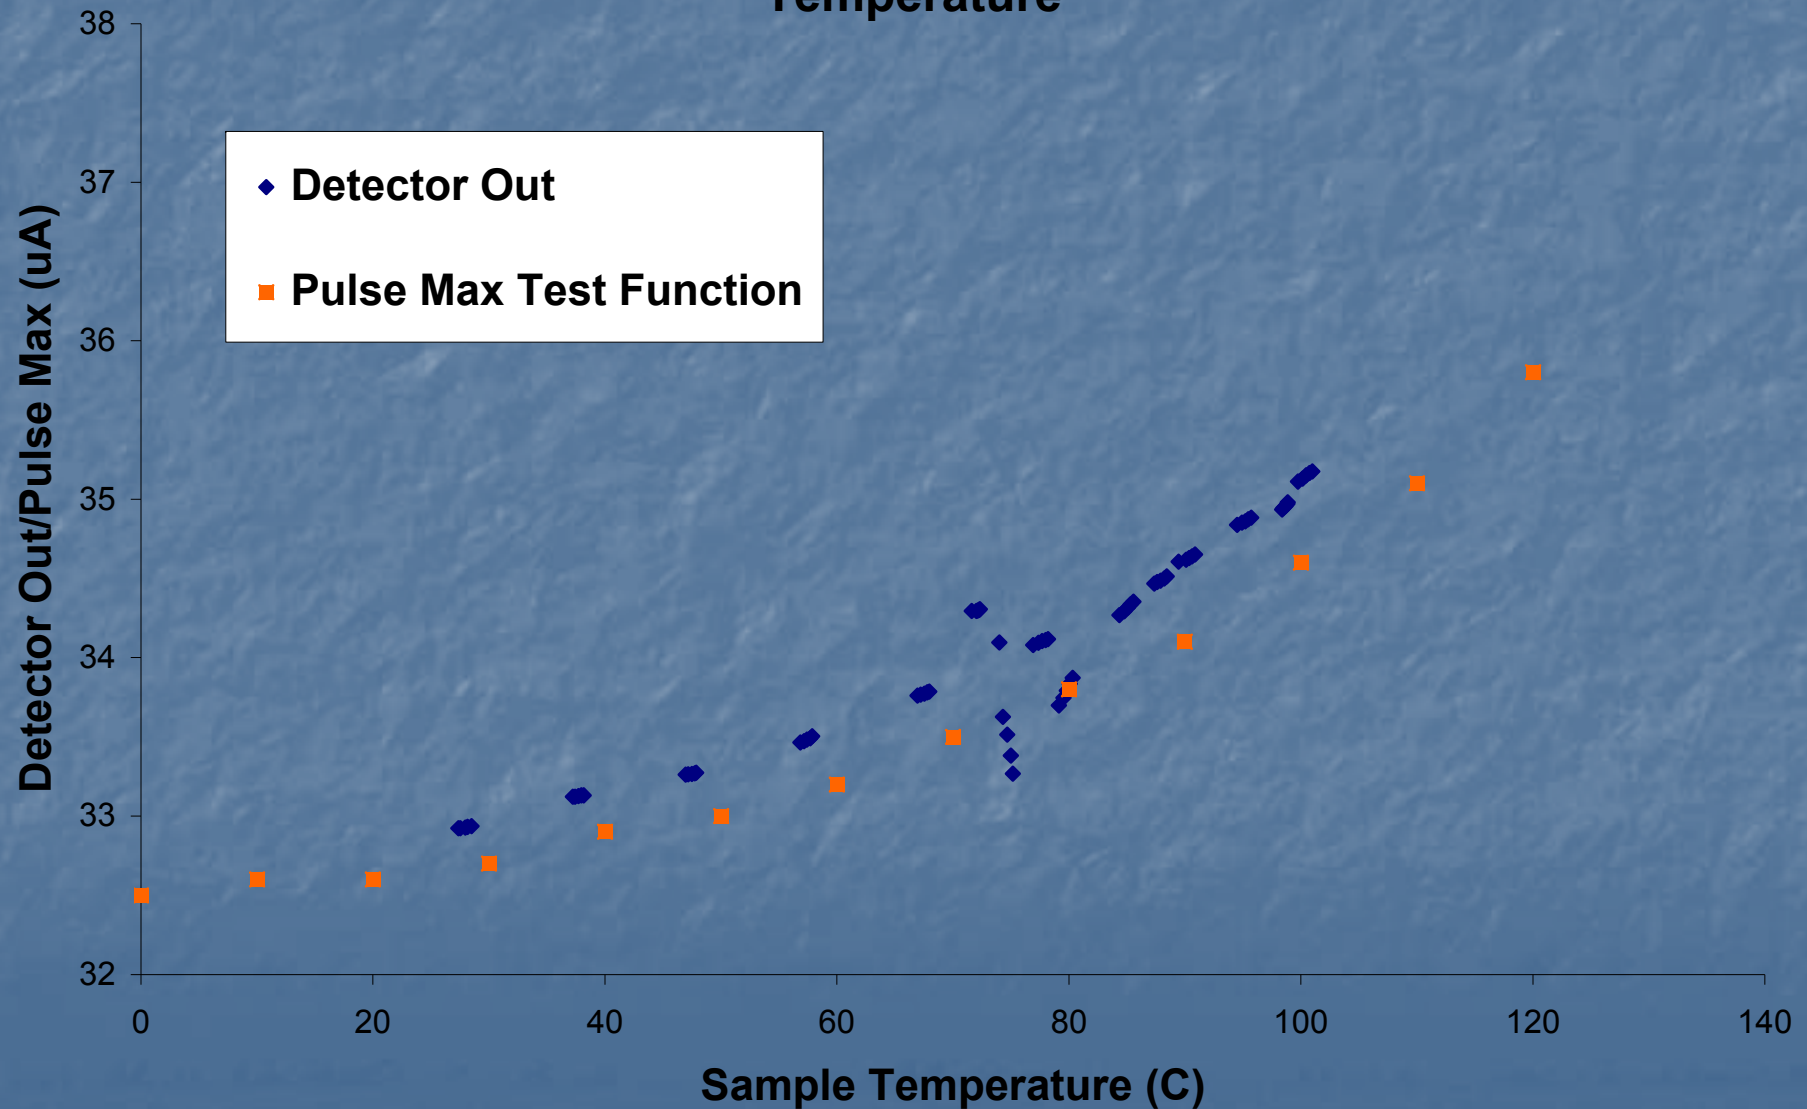

- $P = \Delta T * \frac{dIs}{dT}$

Pulse Max measured over greater time interval, so less prone to background effects

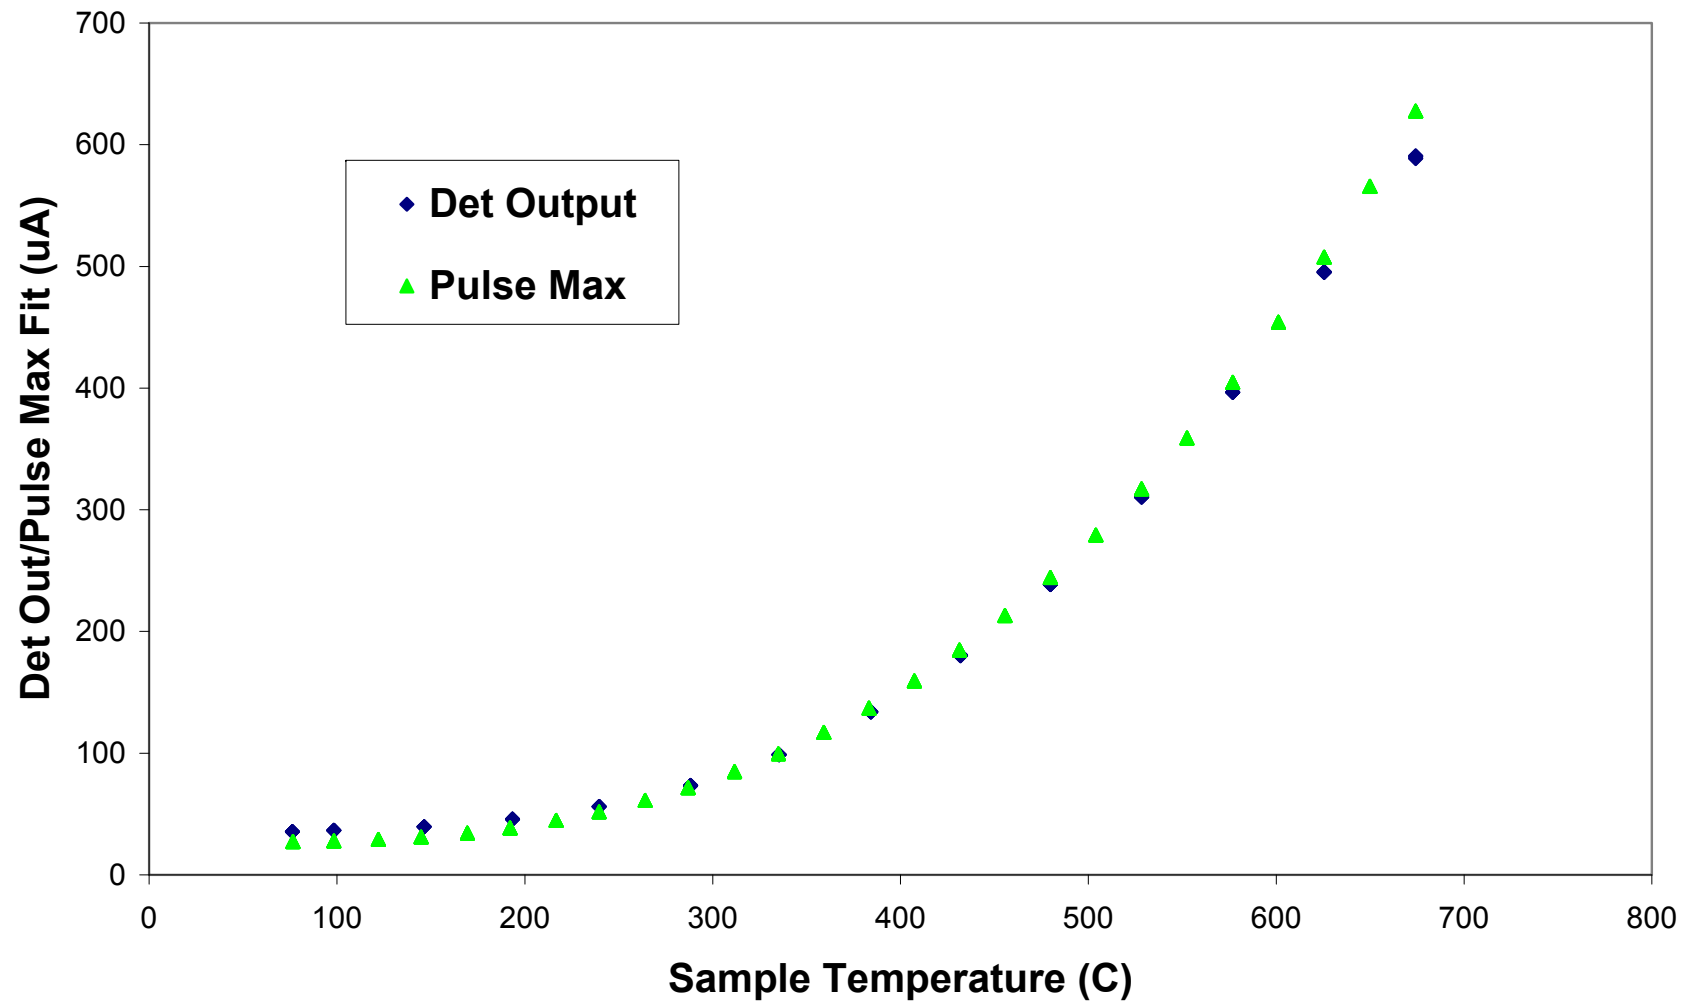

Pulse Max Integral

Detector Out and Pulse Max Test Function vs. Sample Temperature

Pulse Max Integral

Detector Out Compared to Pulse Max Fit for NSKP 18

Graphite Comparison Algorithm

Experiment 3

Basis: 3D Cross Section

Pure Graphite
Standard

Every coated
sample should
have some signal
characteristics of
pure graphite

Coated Sample

Any other signal
measured should
be due to sample
material

Graphite Comparison Algorithm

Need to develop formula to express the comparison technique

Pulse max: $P = \Delta T * \frac{dI_s}{dT}$

Heat Capacity: $C_p = Q / (m * \Delta T) \rightarrow \Delta T = Q / C_p * m$

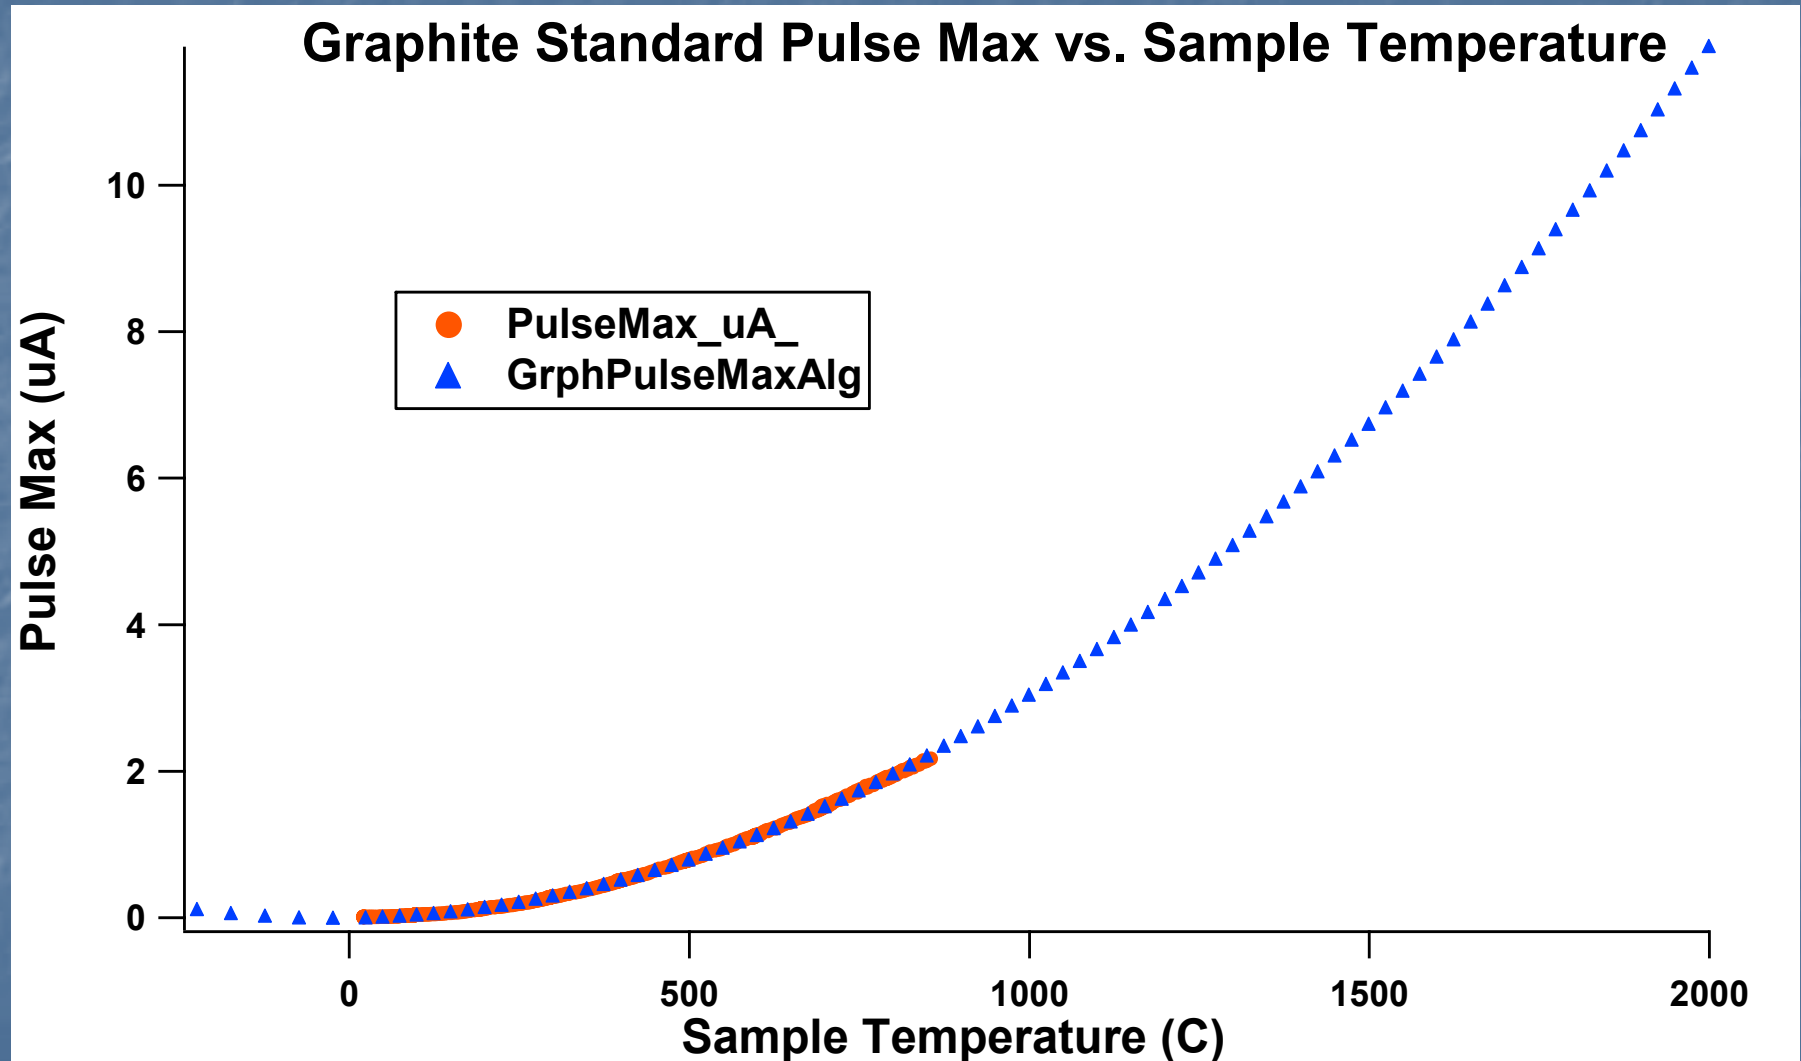

$\rightarrow P * C_p * m = Q * dI_s/dT = Q'$ **Graphite Standard**

$Q' = P(s) * C_p(s) * m(s)$ **Sample Properties**

$C_p(s) = Q' / \{P(s) * m(s)\}$

To make Q' , need C_p and P data for graphite standard

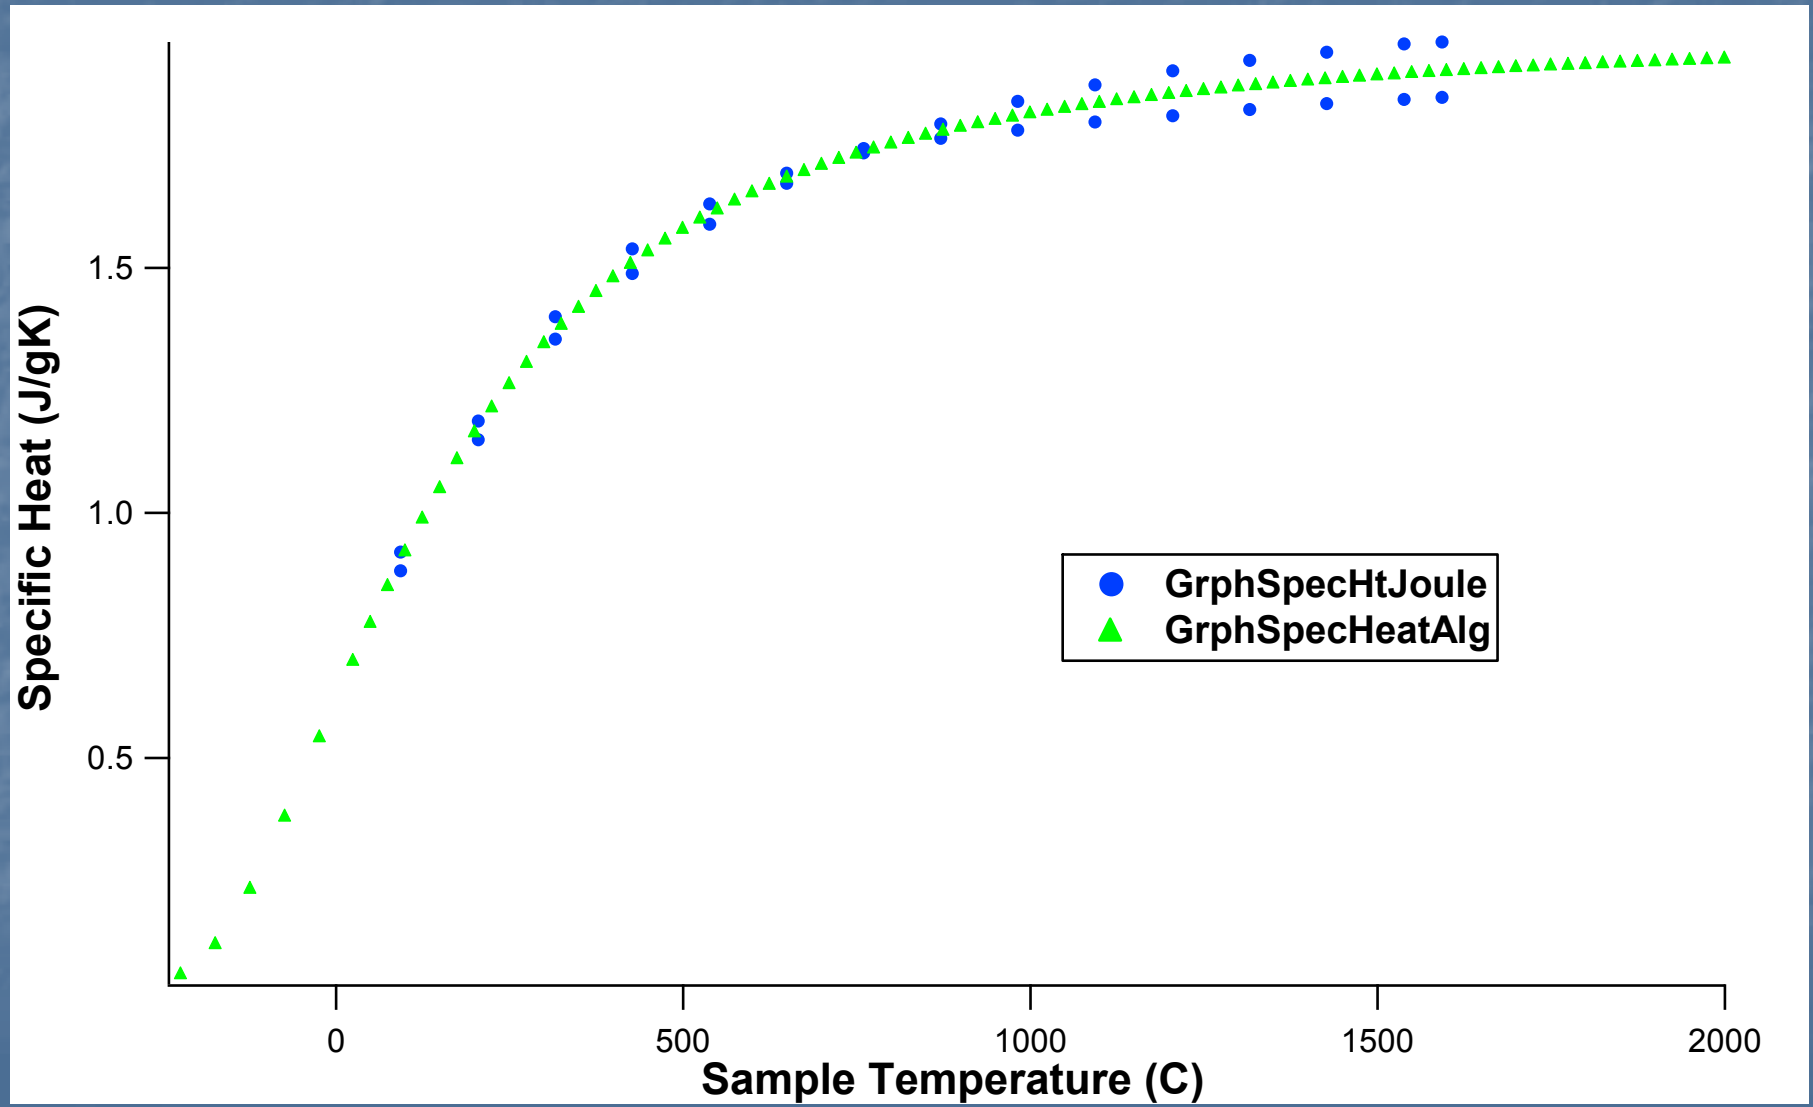

Graphite Comparison Algorithm

*From Lab measurements

Graphite Comparison Algorithm

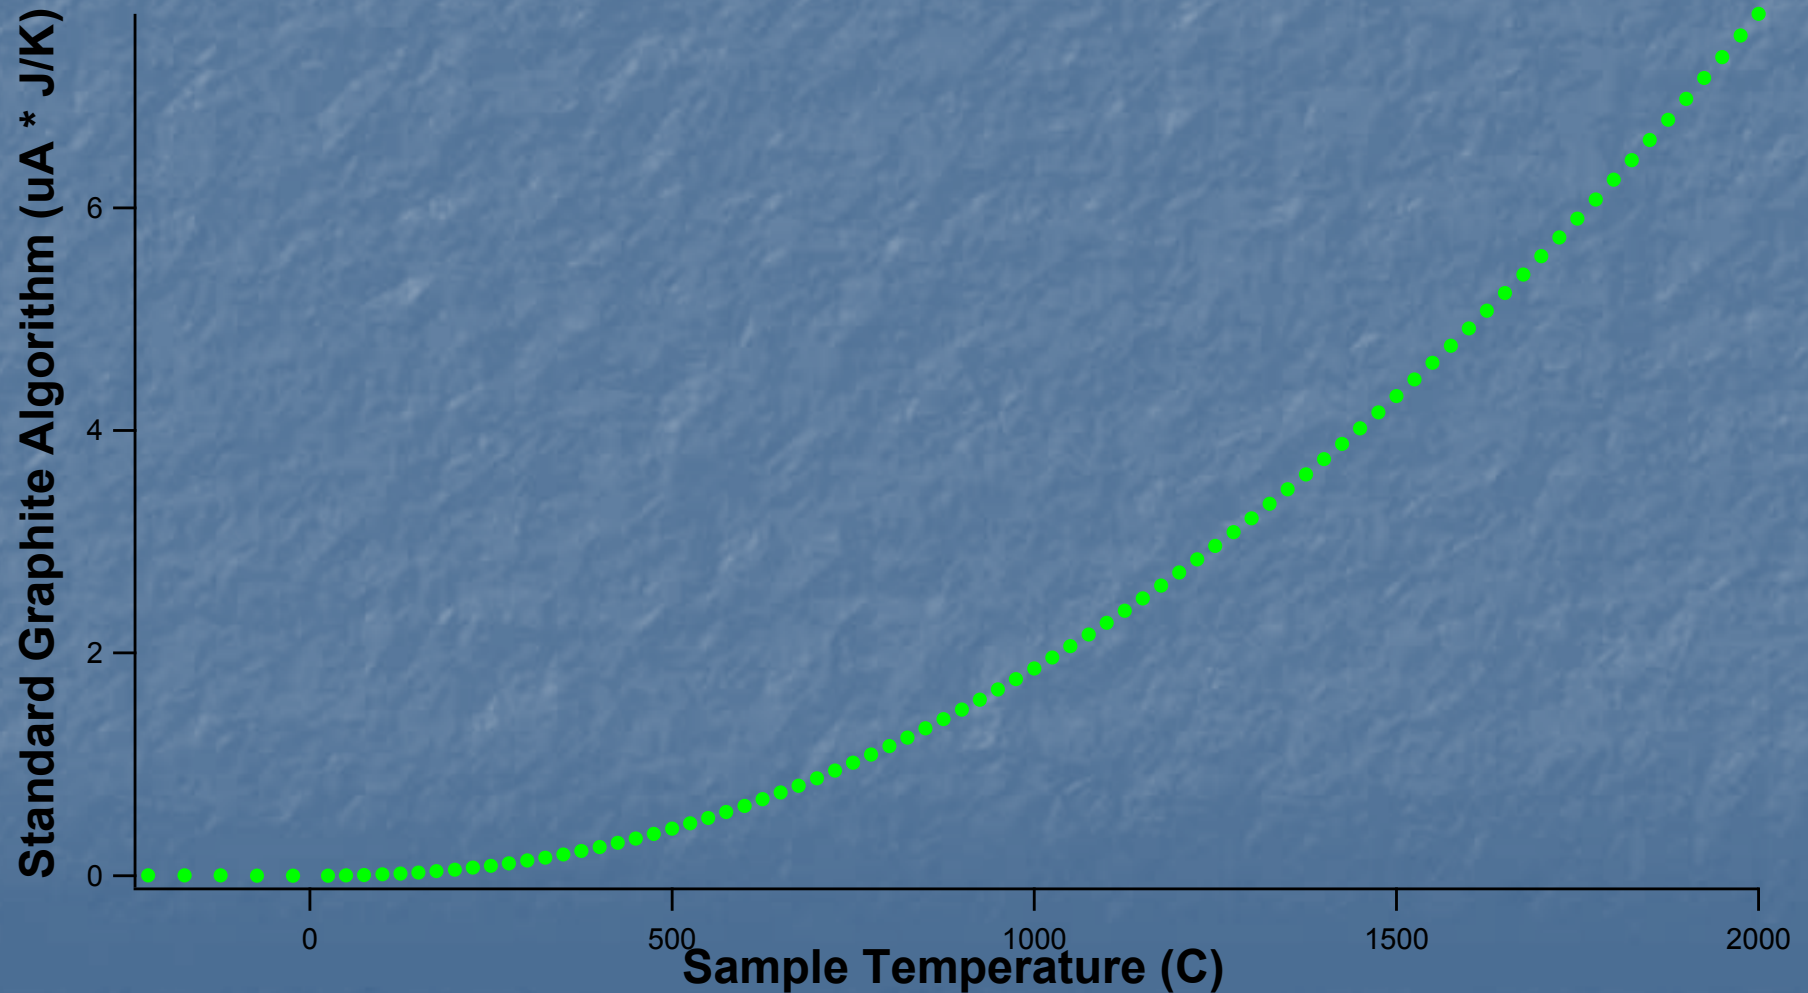

Graphite Specific Heat vs. Sample Temperature

*From Reference material

Graphite Comparison Algorithm

Standard Graphite Algorithm, Q' , vs. Sample Temperature

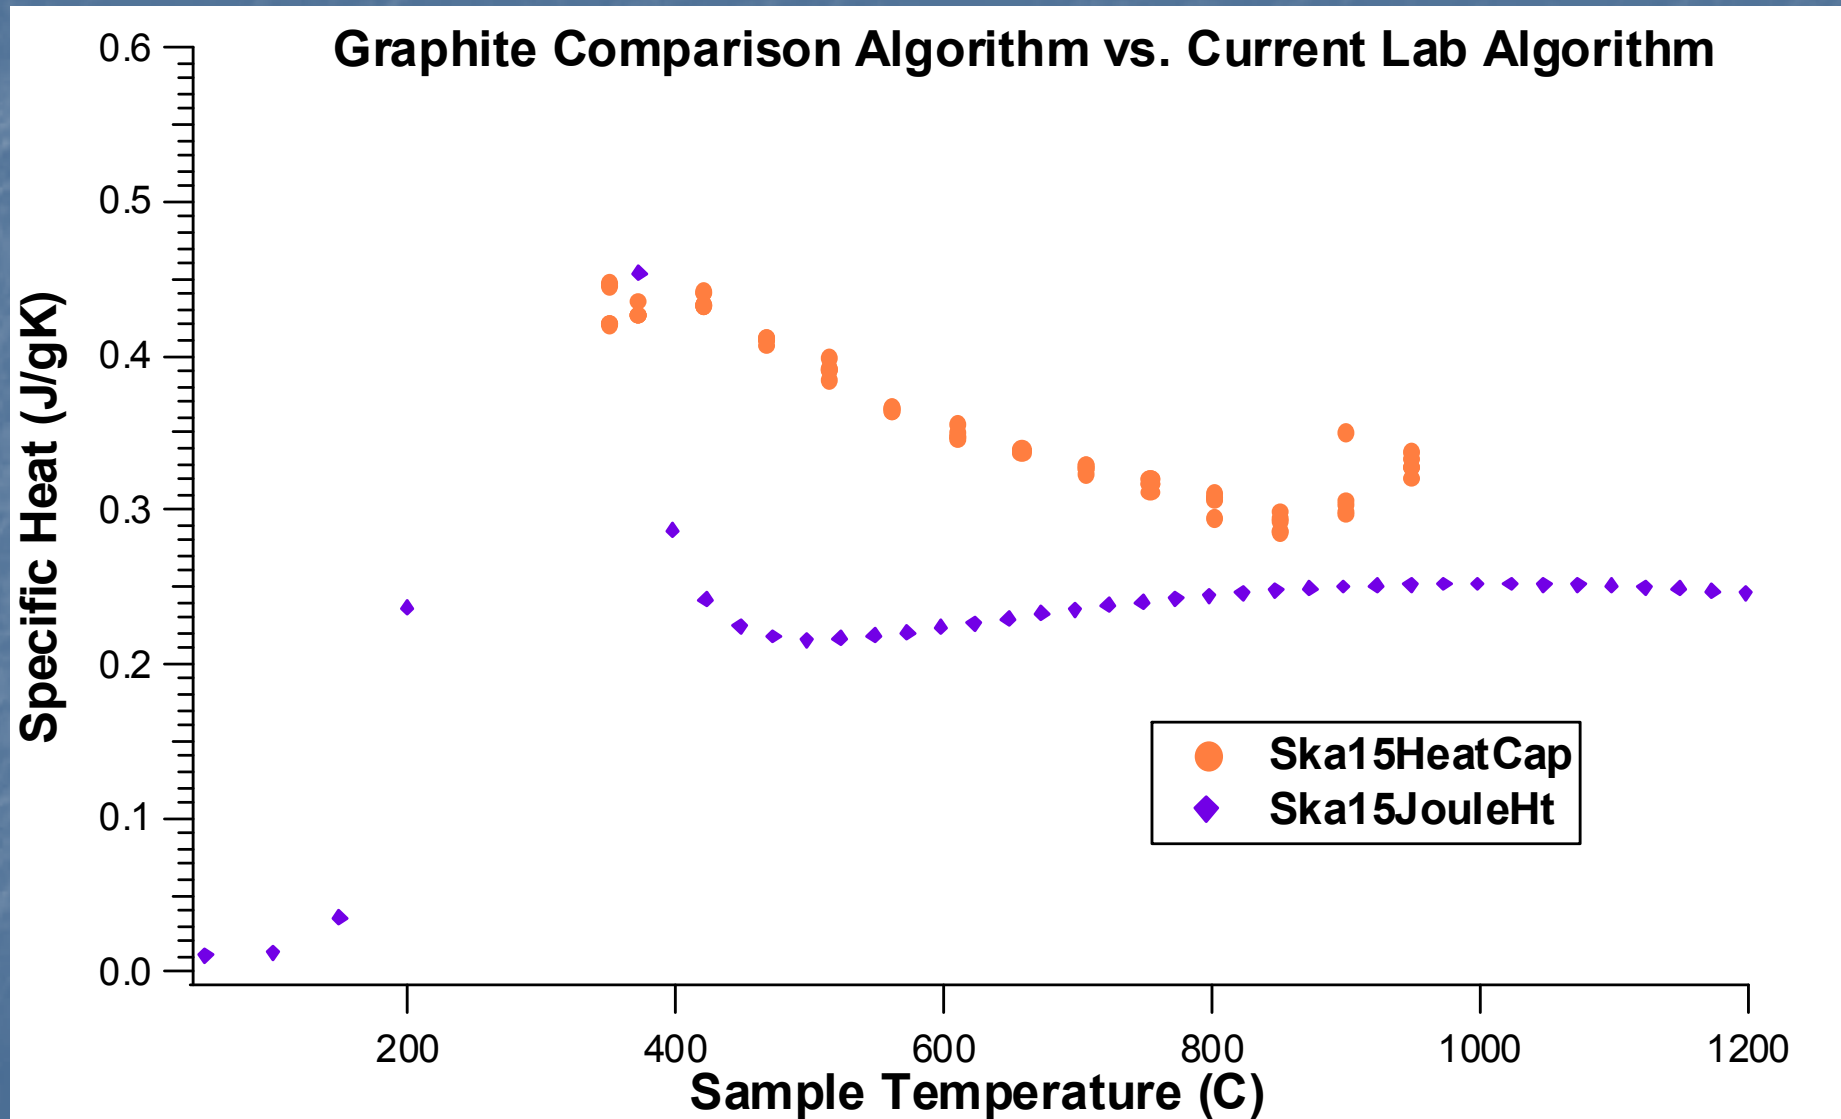

Graphite Comparison Algorithm

$$Q'(T) = -8.7124\text{E-}14 T^4 + 3.4188\text{E-}10 T^3 + 1.5829\text{E-}6 T^2 + 4.0911\text{E-}5 T - 0.02258$$

To test, used a skutterudite, a new thermoelectric material

Dulong-Petit law gave the specific heat of this sample as 0.23 Joules/gK at 430°C, with it increasing slightly as temperature increased

Graphite Comparison Algorithm

Conclusion

Improved heat capacity algorithm achieved after testing multiple algorithms

Gives specific heat measurements in real time, no additional calculations needed

New materials can be measured more accurately

Older materials can be remeasured to find new avenues to pursue in materials research

Future work: Test graphite comparison algorithm using different types of materials, especially standards such as stainless steel, to ensure validity of new algorithm
